3	API	9
4	Release notes	49
5	License	51
6	Indices and tables	53

Freetype python provides bindings for the FreeType library. Only the high-level API is bound.

Freetype-py lives at https://github.com/rougier/freetype-py/, see the installation instructions there.

Contents 1

2 Contents

CHAPTER 1

Usage example

```
import freetype
face = freetype.Face("Vera.ttf")
face.set_char_size( 48*64 )
face.load_char('S')
bitmap = face.glyph.bitmap
print bitmap.buffer
```

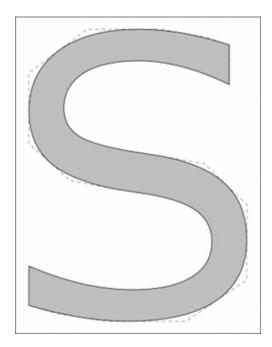

CHAPTER 2

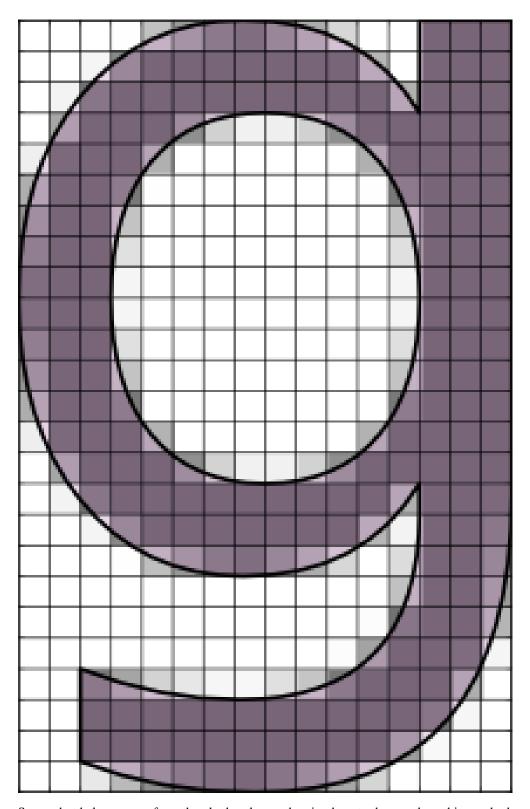

Screenshots

Screenshot below comes from the wordle.py example. No clever tricks here, just brute force.

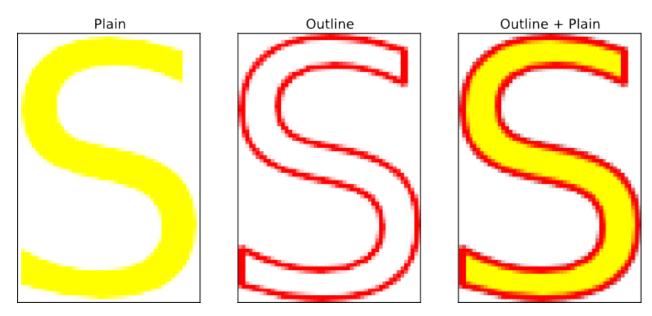

Screenshots below comes from the glyph-vector.py and glyph-vectopr-2.py examples showing how to access a glyph outline information and use it to draw the glyph. Rendering (with Bézier curves) is done using matplotlib.

Screenshot below comes from the glyph-color.py showing how to draw and combine a glyph outline with the regular glyph.

The screenshot below comes from the hello-world.py example showing how to draw text in a bitmap (that has been zoomed in to show antialiasing).

Hello World!

The screenshot below comes from the agg-trick.py example showing an implementation of ideas from the Texts Rasterization Exposures by Maxim Shemarev.

CHAPTER 3

API

3.1 Face

class freetype.Face (path_or_stream, index=0)

FT_Face wrapper

FreeType root face class structure. A face object models a typeface in a font file.

ascender

The typographic ascender of the face, expressed in font units. For font formats not having this information, it is set to 'bbox.yMax'. Only relevant for scalable formats.

attach_file (filename)

Attach data to a face object. Normally, this is used to read additional information for the face object. For example, you can attach an AFM file that comes with a Type 1 font to get the kerning values and other metrics.

Parameters filename - Filename to attach

Note

The meaning of the 'attach' (i.e., what really happens when the new file is read) is not fixed by FreeType itself. It really depends on the font format (and thus the font driver).

Client applications are expected to know what they are doing when invoking this function. Most drivers simply do not implement file attachments.

available_sizes

A list of FT_Bitmap_Size for all bitmap strikes in the face. It is set to NULL if there is no bitmap strike.

bbox

The font bounding box. Coordinates are expressed in font units (see 'units_per_EM'). The box is large enough to contain any glyph from the font. Thus, 'bbox.yMax' can be seen as the 'maximal ascender', and 'bbox.yMin' as the 'minimal descender'. Only relevant for scalable formats.

Note that the bounding box might be off by (at least) one pixel for hinted fonts. See FT_Size_Metrics for further discussion.

charmap

The current active charmap for this face.

charmaps

A list of the charmaps of the face.

descender

The typographic descender of the face, expressed in font units. For font formats not having this information, it is set to 'bbox.yMin'. Note that this field is usually negative. Only relevant for scalable formats.

face_flags

A set of bit flags that give important information about the face; see FT_FACE_FLAG_XXX for the details.

face_index

The index of the face in the font file. It is set to 0 if there is only one face in the font file.

family name

The face's family name. This is an ASCII string, usually in English, which describes the typeface's family (like 'Times New Roman', 'Bodoni', 'Garamond', etc). This is a least common denominator used to list fonts. Some formats (TrueType & OpenType) provide localized and Unicode versions of this string. Applications should use the format specific interface to access them. Can be NULL (e.g., in fonts embedded in a PDF file).

get_advance (gindex, flags)

Retrieve the advance value of a given glyph outline in an FT_Face. By default, the unhinted advance is returned in font units.

Parameters

- gindex The glyph index.
- **flags** A set of bit flags similar to those used when calling FT_Load_Glyph, used to determine what kind of advances you need.

Returns

The advance value, in either font units or 16.16 format.

If FT_LOAD_VERTICAL_LAYOUT is set, this is the vertical advance corresponding to a vertical layout. Otherwise, it is the horizontal advance in a horizontal layout.

get_char_index (charcode)

Return the glyph index of a given character code. This function uses a charmap object to do the mapping.

Parameters charcode - The character code.

Note:

If you use FreeType to manipulate the contents of font files directly, be aware that the glyph index returned by this function doesn't always correspond to the internal indices used within the file. This is done to ensure that value 0 always corresponds to the 'missing glyph'.

get_chars()

This generator function is used to return all unicode character codes in the current charmap of a given face. For each character it also returns the corresponding glyph index.

Returns character code, glyph index

Note: Note that 'agindex' is set to 0 if the charmap is empty. The character code itself can be 0 in two cases: if the charmap is empty or if the value 0 is the first valid character code.

get_first_char()

This function is used to return the first character code in the current charmap of a given face. It also returns the corresponding glyph index.

Returns Glyph index of first character code. 0 if charmap is empty.

Note:

You should use this function with get_next_char to be able to parse all character codes available in a given charmap. The code should look like this:

Note that 'agindex' is set to 0 if the charmap is empty. The result itself can be 0 in two cases: if the charmap is empty or if the value 0 is the first valid character code.

get_format()

Return a string describing the format of a given face, using values which can be used as an X11 FONT_PROPERTY. Possible values are 'TrueType', 'Type 1', 'BDF', 'PCF', 'Type 42', 'CID Type 1', 'CFF', 'PFR', and 'Windows FNT'.

get_fstype()

Return the fsType flags for a font (embedding permissions).

The return value is a tuple containing the freetype enum name as a string and the actual flag as an int

get_glyph_name (agindex, buffer_max=64)

This function is used to return the glyph name for the given charcode.

Parameters

- agindex The glyph index.
- **buffer_max** The maximum number of bytes to use to store the glyph name.
- glyph_name The glyph name, possibly truncated.

get_kerning (left, right, mode=0)

Return the kerning vector between two glyphs of a same face.

Parameters

- left The index of the left glyph in the kern pair.
- right The index of the right glyph in the kern pair.
- **mode** See FT_Kerning_Mode for more information. Determines the scale and dimension of the returned kerning vector.

Note:

Only horizontal layouts (left-to-right & right-to-left) are supported by this method. Other layouts, or more sophisticated kernings, are out of the scope of this API function – they can be implemented through format-specific interfaces.

get_name_index (name)

Return the glyph index of a given glyph name. This function uses driver specific objects to do the translation.

Parameters name – The glyph name.

get_next_char (charcode, agindex)

This function is used to return the next character code in the current charmap of a given face following the value 'charcode', as well as the corresponding glyph index.

Parameters

• **charcode** – The starting character code.

3.1. Face 11

• agindex – Glyph index of next character code. 0 if charmap is empty.

Note:

You should use this function with FT_Get_First_Char to walk over all character codes available in a given charmap. See the note for this function for a simple code example.

Note that 'agindex' is set to 0 when there are no more codes in the charmap.

get sfnt name(index)

Retrieve a string of the SFNT 'name' table for a given index

Parameters index - The index of the 'name' string.

Note:

The 'string' array returned in the 'aname' structure is not null-terminated. The application should deallocate it if it is no longer in use.

Use FT_Get_Sfnt_Name_Count to get the total number of available 'name' table entries, then do a loop until you get the right platform, encoding, and name ID.

glyph

The face's associated glyph slot(s).

has_fixed_sizes

True whenever a face object contains some embedded bitmaps. See the 'available_sizes' field of the FT_FaceRec structure.

has_glyph_names

True whenever a face object contains some glyph names that can be accessed through FT_Get_Glyph_Name.

has_horizontal

True whenever a face object contains horizontal metrics (this is true for all font formats though).

has_kerning

True whenever a face object contains kerning data that can be accessed with FT_Get_Kerning.

has_multiple_masters

True whenever a face object contains some multiple masters. The functions provided by FT_MULTIPLE_MASTERS_H are then available to choose the exact design you want.

has_vertical

True whenever a face object contains vertical metrics.

height

The height is the vertical distance between two consecutive baselines, expressed in font units. It is always positive. Only relevant for scalable formats.

is_cid_keyed

True whenever a face object contains a CID-keyed font. See the discussion of FT_FACE_FLAG_CID_KEYED for more details.

If this macro is true, all functions defined in FT_CID_H are available.

is fixed width

True whenever a face object contains a font face that contains fixed-width (or 'monospace', 'fixed-pitch', etc.) glyphs.

is_scalable

true whenever a face object contains a scalable font face (true for TrueType, Type 1, Type 42, CID, Open-Type/CFF, and PFR font formats.

is sfnt

true whenever a face object contains a font whose format is based on the SFNT storage scheme. This usually means: TrueType fonts, OpenType fonts, as well as SFNT-based embedded bitmap fonts.

If this macro is true, all functions defined in FT_SFNT_NAMES_H and FT_TRUETYPE_TABLES_H are available.

is_tricky

True whenever a face represents a 'tricky' font. See the discussion of FT_FACE_FLAG_TRICKY for more details.

load_char (char, flags=4)

A function used to load a single glyph into the glyph slot of a face object, according to its character code.

Parameters

- **char** The glyph's character code, according to the current charmap used in the face.
- **flags** A flag indicating what to load for this glyph. The FT_LOAD_XXX constants can be used to control the glyph loading process (e.g., whether the outline should be scaled, whether to load bitmaps or not, whether to hint the outline, etc).

Note:

This function simply calls FT_Get_Char_Index and FT_Load_Glyph.

load_glyph (index, flags=4)

A function used to load a single glyph into the glyph slot of a face object.

Parameters

- index The index of the glyph in the font file. For CID-keyed fonts (either in PS or in CFF format) this argument specifies the CID value.
- **flags** A flag indicating what to load for this glyph. The FT_LOAD_XXX constants can be used to control the glyph loading process (e.g., whether the outline should be scaled, whether to load bitmaps or not, whether to hint the outline, etc).

Note:

The loaded glyph may be transformed. See FT_Set_Transform for the details.

For subsetted CID-keyed fonts, 'FT_Err_Invalid_Argument' is returned for invalid CID values (this is, for CID values which don't have a corresponding glyph in the font). See the discussion of the FT FACE FLAG CID KEYED flag for more details.

max_advance_height

The maximal advance height, in font units, for all glyphs in this face. This is only relevant for vertical layouts, and is set to 'height' for fonts that do not provide vertical metrics. Only relevant for scalable formats.

max advance width

The maximal advance width, in font units, for all glyphs in this face. This can be used to make word wrapping computations faster. Only relevant for scalable formats.

num faces

The number of faces in the font file. Some font formats can have multiple faces in a font file.

num_fixed_sizes

The number of bitmap strikes in the face. Even if the face is scalable, there might still be bitmap strikes, which are called 'sbits' in that case.

3.1. Face 13

num_glyphs

The number of glyphs in the face. If the face is scalable and has sbits (see 'num_fixed_sizes'), it is set to the number of outline glyphs.

For CID-keyed fonts, this value gives the highest CID used in the font.

postscript_name

ASCII PostScript name of face, if available. This only works with PostScript and TrueType fonts.

select charmap(encoding)

Select a given charmap by its encoding tag (as listed in 'freetype.h').

Note:

This function returns an error if no charmap in the face corresponds to the encoding queried here.

Because many fonts contain more than a single cmap for Unicode encoding, this function has some special code to select the one which covers Unicode best ('best' in the sense that a UCS-4 cmap is preferred to a UCS-2 cmap). It is thus preferable to FT_Set_Charmap in this case.

select_size(strike_index)

Select a bitmap strike.

Parameters strike_index - The index of the bitmap strike in the 'available_sizes' field of Face object.

set_char_size (width=0, height=0, hres=72, vres=72)

This function calls FT_Request_Size to request the nominal size (in points).

Parameters

- width (float) The nominal width, in 26.6 fractional points.
- height (float) The nominal height, in 26.6 fractional points.
- **hres** (float) The horizontal resolution in dpi.
- **vres** (float) The vertical resolution in dpi.

Note

If either the character width or height is zero, it is set equal to the other value.

If either the horizontal or vertical resolution is zero, it is set equal to the other value.

A character width or height smaller than 1pt is set to 1pt; if both resolution values are zero, they are set to 72dpi.

Don't use this function if you are using the FreeType cache API.

set charmap(charmap)

Select a given charmap for character code to glyph index mapping.

Parameters charmap – A handle to the selected charmap, or an index to face->charmaps[]

set_pixel_sizes (width, height)

This function calls FT_Request_Size to request the nominal size (in pixels).

Parameters

- width The nominal width, in pixels.
- **height** The nominal height, in pixels.

set transform(matrix, delta)

A function used to set the transformation that is applied to glyph images when they are loaded into a glyph slot through FT Load Glyph.

Parameters matrix – A pointer to the transformation's 2x2 matrix. Use 0 for the identity matrix

Parm delta A pointer to the translation vector. Use 0 for the null vector.

Note:

The transformation is only applied to scalable image formats after the glyph has been loaded. It means that hinting is unaltered by the transformation and is performed on the character size given in the last call to FT Set Char Size or FT Set Pixel Sizes.

Note that this also transforms the 'face.glyph.advance' field, but not the values in 'face.glyph.metrics'.

sfnt name count

Number of name strings in the SFNT 'name' table.

size

The current active size for this face.

style_flags

A set of bit flags indicating the style of the face; see FT_STYLE_FLAG_XXX for the details.

style_name

The face's style name. This is an ASCII string, usually in English, which describes the typeface's style (like 'Italic', 'Bold', 'Condensed', etc). Not all font formats provide a style name, so this field is optional, and can be set to NULL. As for 'family_name', some formats provide localized and Unicode versions of this string. Applications should use the format specific interface to access them.

underline_position

The position, in font units, of the underline line for this face. It is the center of the underlining stem. Only relevant for scalable formats.

underline_thickness

The thickness, in font units, of the underline for this face. Only relevant for scalable formats.

units_per_EM

The number of font units per EM square for this face. This is typically 2048 for TrueType fonts, and 1000 for Type 1 fonts. Only relevant for scalable formats.

3.2 BBox

class freetype.BBox(bbox)

FT_BBox wrapper.

A structure used to hold an outline's bounding box, i.e., the coordinates of its extrema in the horizontal and vertical directions.

Note

The bounding box is specified with the coordinates of the lower left and the upper right corner. In PostScript, those values are often called (llx,lly) and (urx,ury), respectively.

If 'yMin' is negative, this value gives the glyph's descender. Otherwise, the glyph doesn't descend below the baseline. Similarly, if 'ymax' is positive, this value gives the glyph's ascender.

'xMin' gives the horizontal distance from the glyph's origin to the left edge of the glyph's bounding box. If 'xMin' is negative, the glyph extends to the left of the origin.

xMax

The horizontal maximum (right-most).

3.2. BBox 15

xMin

The horizontal minimum (left-most).

yMax

The vertical maximum (top-most).

yMin

The vertical minimum (bottom-most).

3.3 Size Metrics

class freetype.SizeMetrics(metrics)

The size metrics structure gives the metrics of a size object.

Note

The scaling values, if relevant, are determined first during a size changing operation. The remaining fields are then set by the driver. For scalable formats, they are usually set to scaled values of the corresponding fields in Face

Note that due to glyph hinting, these values might not be exact for certain fonts. Thus they must be treated as unreliable with an error margin of at least one pixel!

Indeed, the only way to get the exact metrics is to render all glyphs. As this would be a definite performance hit, it is up to client applications to perform such computations.

The SizeMetrics structure is valid for bitmap fonts also.

ascender

The ascender in 26.6 fractional pixels. See Face for the details.

descender

The descender in 26.6 fractional pixels. See Face for the details.

height

The height in 26.6 fractional pixels. See Face for the details.

max advance

The maximal advance width in 26.6 fractional pixels. See Face for the details.

x_ppen

The width of the scaled EM square in pixels, hence the term 'ppem' (pixels per EM). It is also referred to as 'nominal width'.

x_scale

A 16.16 fractional scaling value used to convert horizontal metrics from font units to 26.6 fractional pixels. Only relevant for scalable font formats.

y_pem

The height of the scaled EM square in pixels, hence the term 'ppem' (pixels per EM). It is also referred to as 'nominal height'.

y_scale

A 16.16 fractional scaling value used to convert vertical metrics from font units to 26.6 fractional pixels. Only relevant for scalable font formats.

3.4 Bitmap size

class freetype.BitmapSize(size)

FT_Bitmap_Size wrapper

This structure models the metrics of a bitmap strike (i.e., a set of glyphs for a given point size and resolution) in a bitmap font. It is used for the 'available_sizes' field of Face.

Note

Windows FNT: The nominal size given in a FNT font is not reliable. Thus when the driver finds it incorrect, it sets 'size' to some calculated values and sets 'x_ppem' and 'y_ppem' to the pixel width and height given in the font, respectively.

TrueType embedded bitmaps: 'size', 'width', and 'height' values are not contained in the bitmap strike itself. They are computed from the global font parameters.

height

The vertical distance, in pixels, between two consecutive baselines. It is always positive.

size

The nominal size of the strike in 26.6 fractional points. This field is not very useful.

width

The average width, in pixels, of all glyphs in the strike.

x_ppem

The horizontal ppem (nominal width) in 26.6 fractional pixels.

y_ppem

The vertical ppem (nominal width) in 26.6 fractional pixels.

3.5 Bitmap

class freetype.Bitmap(bitmap)

FT_Bitmap wrapper

A structure used to describe a bitmap or pixmap to the raster. Note that we now manage pixmaps of various depths through the 'pixel_mode' field.

Note:

For now, the only pixel modes supported by FreeType are mono and grays. However, drivers might be added in the future to support more 'colorful' options.

buffer

A typeless pointer to the bitmap buffer. This value should be aligned on 32-bit boundaries in most cases.

num_grays

This field is only used with FT_PIXEL_MODE_GRAY; it gives the number of gray levels used in the bitmap.

palette

A typeless pointer to the bitmap palette; this field is intended for paletted pixel modes. Not used currently.

palette mode

This field is intended for paletted pixel modes; it indicates how the palette is stored. Not used currently.

3.4. Bitmap size

pitch

The pitch's absolute value is the number of bytes taken by one bitmap row, including padding. However, the pitch is positive when the bitmap has a 'down' flow, and negative when it has an 'up' flow. In all cases, the pitch is an offset to add to a bitmap pointer in order to go down one row.

Note that 'padding' means the alignment of a bitmap to a byte border, and FreeType functions normally align to the smallest possible integer value.

For the B/W rasterizer, 'pitch' is always an even number.

To change the pitch of a bitmap (say, to make it a multiple of 4), use FT_Bitmap_Convert. Alternatively, you might use callback functions to directly render to the application's surface; see the file 'example2.py' in the tutorial for a demonstration.

pixel_mode

The pixel mode, i.e., how pixel bits are stored. See FT_Pixel_Mode for possible values.

rows

The number of bitmap rows.

width

The number of pixels in bitmap row.

3.6 Charmap

class freetype.Charmap(charmap)

FT_Charmap wrapper.

A handle to a given character map. A charmap is used to translate character codes in a given encoding into glyph indexes for its parent's face. Some font formats may provide several charmaps per font.

Each face object owns zero or more charmaps, but only one of them can be 'active' and used by FT_Get_Char_Index or FT_Load_Char.

The list of available charmaps in a face is available through the 'face.num_charmaps' and 'face.charmaps' fields of FT_FaceRec.

The currently active charmap is available as 'face.charmap'. You should call FT_Set_Charmap to change it.

Note:

When a new face is created (either through FT_New_Face or FT_Open_Face), the library looks for a Unicode charmap within the list and automatically activates it.

See also:

See FT_CharMapRec for the publicly accessible fields of a given character map.

cmap_format

The format of 'charmap'. If 'charmap' doesn't belong to a TrueType/sfnt face, return -1.

cmap_language_id

The language ID of 'charmap'. If 'charmap' doesn't belong to a TrueType/sfnt face, just return 0 as the default value.

encoding

An FT_Encoding tag identifying the charmap. Use this with FT_Select_Charmap.

encoding id

A platform specific encoding number. This also comes from the TrueType specification and should be emulated similarly.

encoding_name

A platform specific encoding name. This also comes from the TrueType specification and should be emulated similarly.

index

The index into the array of character maps within the face to which 'charmap' belongs. If an error occurs, -1 is returned.

platform_id

An ID number describing the platform for the following encoding ID. This comes directly from the True-Type specification and should be emulated for other formats.

3.7 Outline

class freetype.Outline(outline)

FT_Outline wrapper.

This structure is used to describe an outline to the scan-line converter.

contours

The number of contours in the outline.

flags

A set of bit flags used to characterize the outline and give hints to the scan-converter and hinter on how to convert/grid-fit it. See FT OUTLINE FLAGS.

get_bbox()

Compute the exact bounding box of an outline. This is slower than computing the control box. However, it uses an advanced algorithm which returns very quickly when the two boxes coincide. Otherwise, the outline Bezier arcs are traversed to extract their extrema.

get_cbox()

Return an outline's 'control box'. The control box encloses all the outline's points, including Bezier control points. Though it coincides with the exact bounding box for most glyphs, it can be slightly larger in some situations (like when rotating an outline which contains Bezier outside arcs).

Computing the control box is very fast, while getting the bounding box can take much more time as it needs to walk over all segments and arcs in the outline. To get the latter, you can use the 'ftbbox' component which is dedicated to this single task.

get_inside_border()

Retrieve the FT StrokerBorder value corresponding to the 'inside' borders of a given outline.

Returns The border index. FT_STROKER_BORDER_RIGHT for empty or invalid outlines.

get_outside_border()

Retrieve the FT_StrokerBorder value corresponding to the 'outside' borders of a given outline.

Returns The border index. FT_STROKER_BORDER_RIGHT for empty or invalid outlines.

points

The number of points in the outline.

tags

A list of 'n_points' chars, giving each outline point's type.

If bit 0 is unset, the point is 'off' the curve, i.e., a Bezier control point, while it is 'on' if set.

Bit 1 is meaningful for 'off' points only. If set, it indicates a third-order Bezier arc control point; and a second-order control point if unset.

3.7. Outline 19

If bit 2 is set, bits 5-7 contain the drop-out mode (as defined in the OpenType specification; the value is the same as the argument to the SCANMODE instruction).

Bits 3 and 4 are reserved for internal purposes.

3.8 Glyph

```
class freetype.Glyph(glyph)
```

FT_Glyph wrapper.

The root glyph structure contains a given glyph image plus its advance width in 16.16 fixed float format.

format

The format of the glyph's image.

```
get_cbox (bbox_mode)
```

Return an outline's 'control box'. The control box encloses all the outline's points, including Bezier control points. Though it coincides with the exact bounding box for most glyphs, it can be slightly larger in some situations (like when rotating an outline which contains Bezier outside arcs).

Computing the control box is very fast, while getting the bounding box can take much more time as it needs to walk over all segments and arcs in the outline. To get the latter, you can use the 'ftbbox' component which is dedicated to this single task.

Parameters mode – The mode which indicates how to interpret the returned bounding box values.

Note:

Coordinates are relative to the glyph origin, using the y upwards convention.

If the glyph has been loaded with FT_LOAD_NO_SCALE, 'bbox_mode' must be set to FT_GLYPH_BBOX_UNSCALED to get unscaled font units in 26.6 pixel format. The value FT_GLYPH_BBOX_SUBPIXELS is another name for this constant.

Note that the maximum coordinates are exclusive, which means that one can compute the width and height of the glyph image (be it in integer or 26.6 pixels) as:

width = bbox.xMax - bbox.xMin; height = bbox.yMax - bbox.yMin;

Note also that for 26.6 coordinates, if 'bbox_mode' is set to FT_GLYPH_BBOX_GRIDFIT, the coordinates will also be grid-fitted, which corresponds to:

bbox.xMin = FLOOR(bbox.xMin); bbox.yMin = FLOOR(bbox.yMin); bbox.xMax = CEIL-ING(bbox.xMax); bbox.yMax = CEILING(bbox.yMax);

To get the bbox in pixel coordinates, set 'bbox_mode' to FT_GLYPH_BBOX_TRUNCATE.

To get the bbox in grid-fitted pixel coordinates, set 'bbox_mode' to FT_GLYPH_BBOX_PIXELS.

stroke (stroker, destroy=False)

Stroke a given outline glyph object with a given stroker.

Parameters

- stroker A stroker handle.
- **destroy** A Boolean. If 1, the source glyph object is destroyed on success.

Note:

The source glyph is untouched in case of error.

to bitmap (mode, origin, destroy=False)

Convert a given glyph object to a bitmap glyph object.

Parameters

- mode An enumeration that describes how the data is rendered.
- **origin** A pointer to a vector used to translate the glyph image before rendering. Can be 0 (if no translation). The origin is expressed in 26.6 pixels.

We also detect a plain vector and make a pointer out of it, if that's the case.

• **destroy** – A boolean that indicates that the original glyph image should be destroyed by this function. It is never destroyed in case of error.

Note:

This function does nothing if the glyph format isn't scalable.

The glyph image is translated with the 'origin' vector before rendering.

The first parameter is a pointer to an FT_Glyph handle, that will be replaced by this function (with newly allocated data). Typically, you would use (omitting error handling):

3.9 Bitmap glyph

class freetype.BitmapGlyph(glyph)

FT_BitmapGlyph wrapper.

A structure used for bitmap glyph images. This really is a 'sub-class' of FT_GlyphRec.

bitmap

A descriptor for the bitmap.

format

The format of the glyph's image.

left

The left-side bearing, i.e., the horizontal distance from the current pen position to the left border of the glyph bitmap.

top

The top-side bearing, i.e., the vertical distance from the current pen position to the top border of the glyph bitmap. This distance is positive for upwards y!

3.10 Glyph slot

${f class}$ freetype. ${f GlyphSlot}$ (slot)

FT_GlyphSlot wrapper.

FreeType root glyph slot class structure. A glyph slot is a container where individual glyphs can be loaded, be they in outline or bitmap format.

advance

This shorthand is, depending on FT_LOAD_IGNORE_TRANSFORM, the transformed advance width for the glyph (in 26.6 fractional pixel format). As specified with FT_LOAD_VERTICAL_LAYOUT, it uses either the 'horiAdvance' or the 'vertAdvance' value of 'metrics' field.

3.9. Bitmap glyph 21

bitmap

This field is used as a bitmap descriptor when the slot format is FT_GLYPH_FORMAT_BITMAP. Note that the address and content of the bitmap buffer can change between calls of FT_Load_Glyph and a few other functions.

bitmap_left

This is the bitmap's left bearing expressed in integer pixels. Of course, this is only valid if the format is FT GLYPH FORMAT BITMAP.

bitmap_top

This is the bitmap's top bearing expressed in integer pixels. Remember that this is the distance from the baseline to the top-most glyph scanline, upwards y coordinates being positive.

format

This field indicates the format of the image contained in the glyph slot. Typically FT_GLYPH_FORMAT_BITMAP, FT_GLYPH_FORMAT_OUTLINE, or FT_GLYPH_FORMAT_COMPOSITE, but others are possible.

get_glyph()

A function used to extract a glyph image from a slot. Note that the created FT_Glyph object must be released with FT_Done_Glyph.

linearHoriAdvance

The advance width of the unhinted glyph. Its value is expressed in 16.16 fractional pixels, unless FT_LOAD_LINEAR_DESIGN is set when loading the glyph. This field can be important to perform correct WYSIWYG layout. Only relevant for outline glyphs.

linearVertAdvance

The advance height of the unhinted glyph. Its value is expressed in 16.16 fractional pixels, unless FT_LOAD_LINEAR_DESIGN is set when loading the glyph. This field can be important to perform correct WYSIWYG layout. Only relevant for outline glyphs.

metrics

The metrics of the last loaded glyph in the slot. The returned values depend on the last load flags (see the FT_Load_Glyph API function) and can be expressed either in 26.6 fractional pixels or font units. Note that even when the glyph image is transformed, the metrics are not.

next

In some cases (like some font tools), several glyph slots per face object can be a good thing. As this is rare, the glyph slots are listed through a direct, single-linked list using its 'next' field.

outline

The outline descriptor for the current glyph image if its format is FT_GLYPH_FORMAT_OUTLINE. Once a glyph is loaded, 'outline' can be transformed, distorted, embolded, etc. However, it must not be freed.

3.11 SFNT name

class freetype.SfntName(name)

SfntName wrapper

A structure used to model an SFNT 'name' table entry.

encoding id

The encoding ID for 'string'.

language_id

The language ID for 'string'.

name id

An identifier for 'string'.

platform_id

The platform ID for 'string'.

string

The 'name' string. Note that its format differs depending on the (platform, encoding) pair. It can be a Pascal String, a UTF-16 one, etc.

Generally speaking, the string is not zero-terminated. Please refer to the TrueType specification for details.

string_len

The length of 'string' in bytes.

3.12 Stroker

class freetype.Stroker

FT_Stroker wrapper

This component generates stroked outlines of a given vectorial glyph. It also allows you to retrieve the 'outside' and/or the 'inside' borders of the stroke.

This can be useful to generate 'bordered' glyph, i.e., glyphs displayed with a coloured (and anti-aliased) border around their shape.

begin_subpath(to, _open)

Start a new sub-path in the stroker.

:param to A pointer to the start vector.

Parameters open – A boolean. If 1, the sub-path is treated as an open one.

Note:

This function is useful when you need to stroke a path that is not stored as an 'Outline' object.

conic_to(control, to)

'Draw' a single quadratic Bezier in the stroker's current sub-path, from the last position.

Parameters

- control A pointer to a Bezier control point.
- to A pointer to the destination point.

Note:

You should call this function between 'begin_subpath' and 'end_subpath'.

cubic_to(control1, control2, to)

'Draw' a single quadratic Bezier in the stroker's current sub-path, from the last position.

Parameters

- **control1** A pointer to the first Bezier control point.
- control2 A pointer to second Bezier control point.
- to A pointer to the destination point.

Note:

You should call this function between 'begin_subpath' and 'end_subpath'.

3.12. Stroker 23

end subpath()

Close the current sub-path in the stroker.

Note:

You should call this function after 'begin_subpath'. If the subpath was not 'opened', this function 'draws' a single line segment to the start position when needed.

export (outline)

Call this function after get border counts to export all borders to your own 'Outline' structure.

Note that this function appends the border points and contours to your outline, but does not try to resize its arrays.

Parameters outline – The target outline.

export_border (border, outline)

Call this function after 'get_border_counts' to export the corresponding border to your own 'Outline' structure.

Note that this function appends the border points and contours to your outline, but does not try to resize its arrays.

Parameters

- border The border index.
- outline The target outline.

Note:

Always call this function after get_border_counts to get sure that there is enough room in your 'Outline' object to receive all new data.

When an outline, or a sub-path, is 'closed', the stroker generates two independent 'border' outlines, named 'left' and 'right'

When the outline, or a sub-path, is 'opened', the stroker merges the 'border' outlines with caps. The 'left' border receives all points, while the 'right' border becomes empty.

Use the function export instead if you want to retrieve all borders at once.

get_border_counts(border)

Call this function once you have finished parsing your paths with the stroker. It returns the number of points and contours necessary to export one of the 'border' or 'stroke' outlines generated by the stroker.

Parameters border - The border index.

Returns number of points, number of contours

get counts()

Call this function once you have finished parsing your paths with the stroker. It returns the number of points and contours necessary to export all points/borders from the stroked outline/path.

Returns number of points, number of contours

line_to(to)

'Draw' a single line segment in the stroker's current sub-path, from the last position.

Parameters to – A pointer to the destination point.

Note:

You should call this function between 'begin_subpath' and 'end_subpath'.

parse_outline (outline, opened)

A convenience function used to parse a whole outline with the stroker. The resulting outline(s) can be retrieved later by functions like FT_Stroker_GetCounts and FT_Stroker_Export.

Parameters outline – The source outline.

Pram opened A boolean. If 1, the outline is treated as an open path instead of a closed one.

Note:

If 'opened' is 0 (the default), the outline is treated as a closed path, and the stroker generates two distinct 'border' outlines.

If 'opened' is 1, the outline is processed as an open path, and the stroker generates a single 'stroke' outline.

This function calls 'rewind' automatically.

rewind()

Reset a stroker object without changing its attributes. You should call this function before beginning a new series of calls to FT_Stroker_BeginSubPath or FT_Stroker_EndSubPath.

set (radius, line_cap, line_join, miter_limit)

Reset a stroker object's attributes.

Parameters

- radius The border radius.
- line_cap The line cap style.
- line_join The line join style.
- miter_limit The miter limit for the FT_STROKER_LINEJOIN_MITER style, expressed as 16.16 fixed point value.

Note:

The radius is expressed in the same units as the outline coordinates.

3.13 Constants

3.13.1 FT ENCODINGS

An enumeration used to specify character sets supported by charmaps. Used in the FT_Select_Charmap API function.

FT_ENCODING_NONE

The encoding value 0 is reserved.

FT ENCODING UNICODE

Corresponds to the Unicode character set. This value covers all versions of the Unicode repertoire, including ASCII and Latin-1. Most fonts include a Unicode charmap, but not all of them.

For example, if you want to access Unicode value U+1F028 (and the font contains it), use value 0x1F028 as the input value for FT_Get_Char_Index.

FT_ENCODING_MS_SYMBOL

Corresponds to the Microsoft Symbol encoding, used to encode mathematical symbols in the 32..255 character code range. For more information, see 'http://www.ceviz.net/symbol.htm'.

3.13. Constants 25

FT ENCODING SJIS

Corresponds to Japanese SJIS encoding. More info at at 'http://langsupport.japanreference.com/encoding.shtml'. See note on multi-byte encodings below.

FT ENCODING GB2312

Corresponds to an encoding system for Simplified Chinese as used used in mainland China.

FT ENCODING BIG5

Corresponds to an encoding system for Traditional Chinese as used in Taiwan and Hong Kong.

FT ENCODING WANSUNG

Corresponds to the Korean encoding system known as Wansung. For more information see 'http://www.microsoft.com/typography/unicode/949.txt'.

FT_ENCODING_JOHAB

The Korean standard character set (KS C 5601-1992), which corresponds to MS Windows code page 1361. This character set includes all possible Hangeul character combinations.

FT ENCODING ADOBE LATIN 1

Corresponds to a Latin-1 encoding as defined in a Type 1 PostScript font. It is limited to 256 character codes.

FT ENCODING ADOBE STANDARD

Corresponds to the Adobe Standard encoding, as found in Type 1, CFF, and OpenType/CFF fonts. It is limited to 256 character codes.

FT ENCODING ADOBE EXPERT

Corresponds to the Adobe Expert encoding, as found in Type 1, CFF, and OpenType/CFF fonts. It is limited to 256 character codes.

FT ENCODING ADOBE CUSTOM

Corresponds to a custom encoding, as found in Type 1, CFF, and OpenType/CFF fonts. It is limited to 256 character codes.

FT ENCODING APPLE ROMAN

Corresponds to the 8-bit Apple roman encoding. Many TrueType and OpenType fonts contain a charmap for this encoding, since older versions of Mac OS are able to use it.

FT_ENCODING_OLD_LATIN_2

This value is deprecated and was never used nor reported by FreeType. Don't use or test for it.

3.13.2 FT FACE FLAGS

A list of bit flags used in the 'face_flags' field of the FT_FaceRec structure. They inform client applications of properties of the corresponding face.

FT FACE FLAG SCALABLE

Indicates that the face contains outline glyphs. This doesn't prevent bitmap strikes, i.e., a face can have both this and and FT_FACE_FLAG_FIXED_SIZES set.

FT_FACE_FLAG_FIXED_SIZES

Indicates that the face contains bitmap strikes. See also the 'num_fixed_sizes' and 'available_sizes' fields of FT_FaceRec.

FT FACE FLAG FIXED WIDTH

Indicates that the face contains fixed-width characters (like Courier, Lucido, MonoType, etc.).

FT FACE FLAG SFNT

Indicates that the face uses the 'sfnt' storage scheme. For now, this means TrueType and OpenType.

FT_FACE_FLAG_HORIZONTAL

Indicates that the face contains horizontal glyph metrics. This should be set for all common formats.

FT FACE FLAG VERTICAL

Indicates that the face contains vertical glyph metrics. This is only available in some formats, not all of them.

FT FACE FLAG KERNING

Indicates that the face contains kerning information. If set, the kerning distance can be retrieved through the function FT_Get_Kerning. Otherwise the function always return the vector (0,0). Note that FreeType doesn't handle kerning data from the 'GPOS' table (as present in some OpenType fonts).

FT FACE FLAG MULTIPLE MASTERS

Indicates that the font contains multiple masters and is capable of interpolating between them. See the multiple-masters specific API for details.

FT_FACE_FLAG_GLYPH_NAMES

Indicates that the font contains glyph names that can be retrieved through FT_Get_Glyph_Name. Note that some TrueType fonts contain broken glyph name tables. Use the function FT_Has_PS_Glyph_Names when needed.

FT_FACE_FLAG_EXTERNAL_STREAM

Used internally by FreeType to indicate that a face's stream was provided by the client application and should not be destroyed when FT_Done_Face is called. Don't read or test this flag.

FT FACE FLAG HINTER

Set if the font driver has a hinting machine of its own. For example, with TrueType fonts, it makes sense to use data from the SFNT 'gasp' table only if the native TrueType hinting engine (with the bytecode interpreter) is available and active.

FT FACE FLAG CID KEYED

Set if the font is CID-keyed. In that case, the font is not accessed by glyph indices but by CID values. For subsetted CID-keyed fonts this has the consequence that not all index values are a valid argument to FT_Load_Glyph. Only the CID values for which corresponding glyphs in the subsetted font exist make FT_Load_Glyph return successfully; in all other cases you get an 'FT_Err_Invalid_Argument' error.

Note that CID-keyed fonts which are in an SFNT wrapper don't have this flag set since the glyphs are accessed in the normal way (using contiguous indices); the 'CID-ness' isn't visible to the application.

FT FACE FLAG TRICKY

Set if the font is 'tricky', this is, it always needs the font format's native hinting engine to get a reasonable result. A typical example is the Chinese font 'mingli.ttf' which uses TrueType bytecode instructions to move and scale all of its subglyphs.

It is not possible to autohint such fonts using FT_LOAD_FORCE_AUTOHINT; it will also ignore FT_LOAD_NO_HINTING. You have to set both FT_LOAD_NO_HINTING and FT_LOAD_NO_AUTOHINT to really disable hinting; however, you probably never want this except for demonstration purposes.

Currently, there are six TrueType fonts in the list of tricky fonts; they are hard-coded in file 'ttobjs.c'.

3.13.3 FT_FSTYPES

A list of bit flags that inform client applications of embedding and subsetting restrictions associated with a font.

FT_FSTYPE_INSTALLABLE_EMBEDDING

Fonts with no fsType bit set may be embedded and permanently installed on the remote system by an application.

FT FSTYPE RESTRICTED LICENSE EMBEDDING

Fonts that have only this bit set must not be modified, embedded or exchanged in any manner without first obtaining permission of the font software copyright owner.

FT_FSTYPE_PREVIEW_AND_PRINT_EMBEDDING

If this bit is set, the font may be embedded and temporarily loaded on the remote system. Documents containing Preview & Print fonts must be opened 'read-only'; no edits can be applied to the document.

3.13. Constants 27

FT FSTYPE EDITABLE EMBEDDING

If this bit is set, the font may be embedded but must only be installed temporarily on other systems. In contrast to Preview & Print fonts, documents containing editable fonts may be opened for reading, editing is permitted, and changes may be saved.

FT_FSTYPE_NO_SUBSETTING

If this bit is set, the font may not be subsetted prior to embedding.

FT_FSTYPE_BITMAP_EMBEDDING_ONLY

If this bit is set, only bitmaps contained in the font may be embedded; no outline data may be embedded. If there are no bitmaps available in the font, then the font is unembeddable.

3.13.4 FT GLYPH BBOX MODES

The mode how the values of FT_Glyph_Get_CBox are returned.

FT_GLYPH_BBOX_UNSCALED

Return unscaled font units.

FT GLYPH BBOX SUBPIXELS

Return unfitted 26.6 coordinates.

FT_GLYPH_BBOX_GRIDFIT

Return grid-fitted 26.6 coordinates.

FT GLYPH BBOX TRUNCATE

Return coordinates in integer pixels.

FT GLYPH BBOX PIXELS

Return grid-fitted pixel coordinates.

3.13.5 FT GLYPH FORMATS

An enumeration type used to describe the format of a given glyph image. Note that this version of FreeType only supports two image formats, even though future font drivers will be able to register their own format.

FT_GLYPH_FORMAT_NONE

The value 0 is reserved.

FT GLYPH FORMAT COMPOSITE

The glyph image is a composite of several other images. This format is only used with FT LOAD NO RECURSE, and is used to report compound glyphs (like accented characters).

FT GLYPH FORMAT BITMAP

The glyph image is a bitmap, and can be described as an FT_Bitmap. You generally need to access the 'bitmap' field of the FT_GlyphSlotRec structure to read it.

${\tt FT_GLYPH_FORMAT_OUTLINE}$

The glyph image is a vectorial outline made of line segments and Bezier arcs; it can be described as an FT_Outline; you generally want to access the 'outline' field of the FT_GlyphSlotRec structure to read it.

FT_GLYPH_FORMAT_PLOTTER

The glyph image is a vectorial path with no inside and outside contours. Some Type 1 fonts, like those in the Hershey family, contain glyphs in this format. These are described as FT_Outline, but FreeType isn't currently capable of rendering them correctly.

3.13.6 FT KERNING MODES

An enumeration used to specify which kerning values to return in .. data:: FT Get Kerning.

FT_KERNING_DEFAULT

Return scaled and grid-fitted kerning distances (value is 0).

FT KERNING UNFITTED

Return scaled but un-grid-fitted kerning distances.

FT KERNING UNSCALED

Return the kerning vector in original font units.

3.13.7 FT LCD FILTERS

A list of values to identify various types of LCD filters.

FT LCD FILTER NONE

Do not perform filtering. When used with subpixel rendering, this results in sometimes severe color fringes.

FT LCD FILTER DEFAULT

The default filter reduces color fringes considerably, at the cost of a slight blurriness in the output.

FT LCD FILTER LIGHT

The light filter is a variant that produces less blurriness at the cost of slightly more color fringes than the default one. It might be better, depending on taste, your monitor, or your personal vision.

FT LCD FILTER LEGACY

This filter corresponds to the original libXft color filter. It provides high contrast output but can exhibit really bad color fringes if glyphs are not extremely well hinted to the pixel grid. In other words, it only works well if the TrueType bytecode interpreter is enabled and high-quality hinted fonts are used.

This filter is only provided for comparison purposes, and might be disabled or stay unsupported in the future.

3.13.8 FT_LOAD_FLAGS

A list of bit-field constants used with FT_Load_Glyph to indicate what kind of operations to perform during glyph loading.

FT LOAD DEFAULT

Corresponding to 0, this value is used as the default glyph load operation. In this case, the following happens:

- 1. FreeType looks for a bitmap for the glyph corresponding to the face's current size. If one is found, the function returns. The bitmap data can be accessed from the glyph slot (see note below).
- 2. If no embedded bitmap is searched or found, FreeType looks for a scalable outline. If one is found, it is loaded from the font file, scaled to device pixels, then 'hinted' to the pixel grid in order to optimize it. The outline data can be accessed from the glyph slot (see note below).

Note that by default, the glyph loader doesn't render outlines into bitmaps. The following flags are used to modify this default behaviour to more specific and useful cases.

FT LOAD NO SCALE

Don't scale the outline glyph loaded, but keep it in font units.

This flag implies FT_LOAD_NO_HINTING and FT_LOAD_NO_BITMAP, and unsets FT_LOAD_RENDER.

FT LOAD NO HINTING

Disable hinting. This generally generates 'blurrier' bitmap glyph when the glyph is rendered in any of the anti-aliased modes. See also the note below.

3.13. Constants 29

This flag is implied by FT_LOAD_NO_SCALE.

FT LOAD RENDER

Call FT_Render_Glyph after the glyph is loaded. By default, the glyph is rendered in FT_RENDER_MODE_NORMAL mode. This can be overridden by FT_LOAD_TARGET_XXX or FT_LOAD_MONOCHROME.

This flag is unset by FT LOAD NO SCALE.

FT_LOAD_NO_BITMAP

Ignore bitmap strikes when loading. Bitmap-only fonts ignore this flag.

FT_LOAD_NO_SCALE always sets this flag.

FT LOAD VERTICAL LAYOUT

Load the glyph for vertical text layout. Don't use it as it is problematic currently.

FT LOAD FORCE AUTOHINT

Indicates that the auto-hinter is preferred over the font's native hinter. See also the note below.

FT_LOAD_CROP_BITMAP

Indicates that the font driver should crop the loaded bitmap glyph (i.e., remove all space around its black bits). Not all drivers implement this.

FT LOAD PEDANTIC

Indicates that the font driver should perform pedantic verifications during glyph loading. This is mostly used to detect broken glyphs in fonts. By default, FreeType tries to handle broken fonts also.

FT LOAD IGNORE GLOBAL ADVANCE WIDTH

Indicates that the font driver should ignore the global advance width defined in the font. By default, that value is used as the advance width for all glyphs when the face has FT_FACE_FLAG_FIXED_WIDTH set.

This flag exists for historical reasons (to support buggy CJK fonts).

FT LOAD NO RECURSE

This flag is only used internally. It merely indicates that the font driver should not load composite glyphs recursively. Instead, it should set the 'num_subglyph' and 'subglyphs' values of the glyph slot accordingly, and set 'glyph->format' to FT_GLYPH_FORMAT_COMPOSITE.

The description of sub-glyphs is not available to client applications for now.

This flag implies FT_LOAD_NO_SCALE and FT_LOAD_IGNORE_TRANSFORM.

FT LOAD IGNORE TRANSFORM

Indicates that the transform matrix set by FT_Set_Transform should be ignored.

FT LOAD MONOCHROME

This flag is used with FT_LOAD_RENDER to indicate that you want to render an outline glyph to a 1-bit monochrome bitmap glyph, with 8 pixels packed into each byte of the bitmap data.

Note that this has no effect on the hinting algorithm used. You should rather use FT_LOAD_TARGET_MONO so that the monochrome-optimized hinting algorithm is used.

FT_LOAD_LINEAR_DESIGN

Indicates that the 'linearHoriAdvance' and 'linearVertAdvance' fields of FT_GlyphSlotRec should be kept in font units. See FT_GlyphSlotRec for details.

FT_LOAD_NO_AUTOHINT

Disable auto-hinter. See also the note below.

3.13.9 FT LOAD TARGETS

A list of values that are used to select a specific hinting algorithm to use by the hinter. You should OR one of these values to your 'load_flags' when calling FT_Load_Glyph.

Note that font's native hinters may ignore the hinting algorithm you have specified (e.g., the TrueType bytecode interpreter). You can set .. data:: FT_LOAD_FORCE_AUTOHINT to ensure that the auto-hinter is used.

Also note that FT_LOAD_TARGET_LIGHT is an exception, in that it always implies FT_LOAD_FORCE_AUTOHINT.

FT_LOAD_TARGET_NORMAL

This corresponds to the default hinting algorithm, optimized for standard gray-level rendering. For monochrome output, use FT LOAD TARGET MONO instead.

FT_LOAD_TARGET_LIGHT

A lighter hinting algorithm for non-monochrome modes. Many generated glyphs are more fuzzy but better resemble its original shape. A bit like rendering on Mac OS X.

As a special exception, this target implies FT_LOAD_FORCE_AUTOHINT.

FT LOAD TARGET MONO

Strong hinting algorithm that should only be used for monochrome output. The result is probably unpleasant if the glyph is rendered in non-monochrome modes.

FT_LOAD_TARGET_LCD

A variant of FT_LOAD_TARGET_NORMAL optimized for horizontally decimated LCD displays.

FT LOAD TARGET LCD V

A variant of FT_LOAD_TARGET_NORMAL optimized for vertically decimated LCD displays.

3.13.10 FT OPEN MODES

A list of bit-field constants used within the 'flags' field of the .. data:: FT Open Args structure.

FT_OPEN_MEMORY

This is a memory-based stream.

FT OPEN STREAM

Copy the stream from the 'stream' field.

FT OPEN PATHNAME

Create a new input stream from a C path name.

FT OPEN DRIVER

Use the 'driver' field.

FT_OPEN_PARAMS

Use the 'num_params' and 'params' fields.

3.13.11 FT OUTLINE FLAGS

A list of bit-field constants use for the flags in an outline's 'flags' field.

FT OUTLINE NONE

Value 0 is reserved.

FT_OUTLINE_OWNER

If set, this flag indicates that the outline's field arrays (i.e., 'points', 'flags', and 'contours') are 'owned' by the outline object, and should thus be freed when it is destroyed.

3.13. Constants 31

FT OUTLINE EVEN ODD FILL

By default, outlines are filled using the non-zero winding rule. If set to 1, the outline will be filled using the even-odd fill rule (only works with the smooth rasterizer).

FT OUTLINE REVERSE FILL

By default, outside contours of an outline are oriented in clock-wise direction, as defined in the TrueType specification. This flag is set if the outline uses the opposite direction (typically for Type 1 fonts). This flag is ignored by the scan converter.

FT OUTLINE IGNORE DROPOUTS

By default, the scan converter will try to detect drop-outs in an outline and correct the glyph bitmap to ensure consistent shape continuity. If set, this flag hints the scan-line converter to ignore such cases. See below for more information.

FT OUTLINE SMART DROPOUTS

Select smart dropout control. If unset, use simple dropout control. Ignored if FT_OUTLINE_IGNORE_DROPOUTS is set. See below for more information.

FT_OUTLINE_INCLUDE STUBS

If set, turn pixels on for 'stubs', otherwise exclude them. Ignored if FT_OUTLINE_IGNORE_DROPOUTS is set. See below for more information.

FT OUTLINE HIGH PRECISION

This flag indicates that the scan-line converter should try to convert this outline to bitmaps with the highest possible quality. It is typically set for small character sizes. Note that this is only a hint that might be completely ignored by a given scan-converter.

FT OUTLINE SINGLE PASS

This flag is set to force a given scan-converter to only use a single pass over the outline to render a bitmap glyph image. Normally, it is set for very large character sizes. It is only a hint that might be completely ignored by a given scan-converter.

3.13.12 FT PIXEL MODES

An enumeration type that lists the render modes supported by FreeType 2. Each mode corresponds to a specific type of scanline conversion performed on the outline.

FT_PIXEL_MODE_NONE

Value 0 is reserved.

FT_PIXEL_MODE_MONO

A monochrome bitmap, using 1 bit per pixel. Note that pixels are stored in most-significant order (MSB), which means that the left-most pixel in a byte has value 128.

FT PIXEL MODE GRAY

An 8-bit bitmap, generally used to represent anti-aliased glyph images. Each pixel is stored in one byte. Note that the number of 'gray' levels is stored in the 'num_grays' field of the FT_Bitmap structure (it generally is 256).

FT_PIXEL_MODE_GRAY2

A 2-bit per pixel bitmap, used to represent embedded anti-aliased bitmaps in font files according to the OpenType specification. We haven't found a single font using this format, however.

FT PIXEL MODE GRAY4

A 4-bit per pixel bitmap, representing embedded anti-aliased bitmaps in font files according to the OpenType specification. We haven't found a single font using this format, however.

FT PIXEL MODE LCD

An 8-bit bitmap, representing RGB or BGR decimated glyph images used for display on LCD displays; the bitmap is three times wider than the original glyph image. See also FT RENDER MODE LCD.

FT PIXEL MODE LCD V

An 8-bit bitmap, representing RGB or BGR decimated glyph images used for display on rotated LCD displays; the bitmap is three times taller than the original glyph image. See also FT_RENDER_MODE_LCD_V.

3.13.13 FT RENDER MODES

An enumeration type that lists the render modes supported by FreeType 2. Each mode corresponds to a specific type of scanline conversion performed on the outline.

For bitmap fonts and embedded bitmaps the 'bitmap->pixel_mode' field in the .. data:: FT_GlyphSlotRec structure gives the format of the returned bitmap.

All modes except FT_RENDER_MODE_MONO use 256 levels of opacity.

FT RENDER MODE NORMAL

This is the default render mode; it corresponds to 8-bit anti-aliased bitmaps.

FT RENDER MODE LIGHT

This is equivalent to FT_RENDER_MODE_NORMAL. It is only defined as a separate value because render modes are also used indirectly to define hinting algorithm selectors. See FT_LOAD_TARGET_XXX for details.

FT RENDER MODE MONO

This mode corresponds to 1-bit bitmaps (with 2 levels of opacity).

FT RENDER MODE LCD

This mode corresponds to horizontal RGB and BGR sub-pixel displays like LCD screens. It produces 8-bit bitmaps that are 3 times the width of the original glyph outline in pixels, and which use the FT_PIXEL_MODE_LCD mode.

FT_RENDER_MODE_LCD_V

This mode corresponds to vertical RGB and BGR sub-pixel displays (like PDA screens, rotated LCD displays, etc.). It produces 8-bit bitmaps that are 3 times the height of the original glyph outline in pixels and use the FT_PIXEL_MODE_LCD_V mode.

3.13.14 FT STROKER BORDERS

These values are used to select a given stroke border in .. data:: FT_Stroker_GetBorderCounts and FT Stroker ExportBorder.

FT_STROKER_BORDER_LEFT

Select the left border, relative to the drawing direction.

FT_STROKER_BORDER_RIGHT

Select the right border, relative to the drawing direction.

Note

Applications are generally interested in the 'inside' and 'outside' borders. However, there is no direct mapping between these and the 'left' and 'right' ones, since this really depends on the glyph's drawing orientation, which varies between font formats.

You can however use FT_Outline_GetInsideBorder and FT_Outline_GetOutsideBorder to get these.

3.13.15 FT_STROKER_LINECAPS

These values determine how the end of opened sub-paths are rendered in a stroke.

FT_STROKER_LINECAP_BUTT

The end of lines is rendered as a full stop on the last point itself.

FT STROKER LINECAP ROUND

The end of lines is rendered as a half-circle around the last point.

FT_STROKER_LINECAP_SQUARE

The end of lines is rendered as a square around the last point.

3.13.16 FT_STROKER_LINEJOINS

These values determine how two joining lines are rendered in a stroker.

FT STROKER LINEJOIN ROUND

Used to render rounded line joins. Circular arcs are used to join two lines smoothly.

FT STROKER LINEJOIN BEVEL

Used to render beveled line joins; i.e., the two joining lines are extended until they intersect.

FT_STROKER_LINEJOIN_MITER

Same as beveled rendering, except that an additional line break is added if the angle between the two joining lines is too closed (this is useful to avoid unpleasant spikes in beveled rendering).

3.13.17 FT STYLE FLAGS

A list of bit-flags used to indicate the style of a given face. These are used in the 'style_flags' field of FT_FaceRec.

FT_STYLE_FLAG_ITALIC

Indicates that a given face style is italic or oblique.

FT_STYLE_FLAG_BOLD

Indicates that a given face is bold.

3.13.18 TT_ADOBE_IDS

A list of valid values for the 'encoding_id' for TT_PLATFORM_ADOBE charmaps. This is a FreeType-specific extension!

TT_ADOBE_ID_STANDARD

Adobe standard encoding.

TT ADOBE ID EXPERT

Adobe expert encoding.

TT_ADOBE_ID_CUSTOM

Adobe custom encoding.

TT_ADOBE_ID_LATIN_1

Adobe Latin 1 encoding.

3.13.19 TT APPLE IDS

A list of valid values for the 'encoding_id' for TT_PLATFORM_APPLE_UNICODE charmaps and name entries.

TT_APPLE_ID_DEFAULT

Unicode version 1.0.

TT_APPLE_ID_UNICODE_1_1

Unicode 1.1; specifies Hangul characters starting at U+34xx.

TT_APPLE_ID_ISO_10646

Deprecated (identical to preceding).

TT APPLE ID UNICODE 2 0

Unicode 2.0 and beyond (UTF-16 BMP only).

TT_APPLE_ID_UNICODE_32

Unicode 3.1 and beyond, using UTF-32.

TT APPLE ID VARIANT SELECTOR

From Adobe, not Apple. Not a normal cmap. Specifies variations on a real cmap.

3.13.20 TT MAC IDS

A list of valid values for the 'encoding_id' for TT_PLATFORM_MACINTOSH charmaps and name entries.

- TT_MAC_ID_ROMAN
- TT_MAC_ID_TELUGU
- TT_MAC_ID_GURMUKHI
- TT_MAC_ID_TIBETAN
- TT MAC ID SIMPLIFIED CHINESE

3.13.22 TT_MS_IDS

A list of valid values for the 'encoding_id' for TT_PLATFORM_MICROSOFT charmaps and name entries.

TT MS ID SYMBOL CS

Corresponds to Microsoft symbol encoding. See FT_ENCODING_MS_SYMBOL.

TT_MS_ID_UNICODE_CS

Corresponds to a Microsoft WGL4 charmap, matching Unicode. See FT_ENCODING_UNICODE.

TT_MS_ID_SJIS

Corresponds to SJIS Japanese encoding. See FT_ENCODING_SJIS.

TT_MS_ID_GB2312

Corresponds to Simplified Chinese as used in Mainland China. See FT_ENCODING_GB2312.

TT_MS_ID_BIG_5

Corresponds to Traditional Chinese as used in Taiwan and Hong Kong. See FT ENCODING BIG5.

TT MS ID WANSUNG

Corresponds to Korean Wansung encoding. See FT_ENCODING_WANSUNG.

TT_MS_ID_JOHAB

Corresponds to Johab encoding. See FT_ENCODING_JOHAB.

TT_MS_ID_UCS_4

Corresponds to UCS-4 or UTF-32 charmaps. This has been added to the OpenType specification version 1.4 (mid-2001.)

3.13.23 TT MS LANGIDS

Possible values of the language identifier field in the name records of the TTF 'name' table if the 'platform' identifier code is TT PLATFORM MICROSOFT.

- TT MS LANGID SANSKRIT INDIA

- TT_NAME_ID_CID_FINDFONT_NAME
- TT_NAME_ID_WWS_FAMILY
- TT_NAME_ID_WWS_SUBFAMILY

3.13.25 TT PLATFORMS

A list of valid values for the 'platform_id' identifier code in FT_CharMapRec and FT_SfntName structures.

TT_PLATFORM_APPLE_UNICODE

Used by Apple to indicate a Unicode character map and/or name entry. See TT_APPLE_ID_XXX for corresponding 'encoding_id' values. Note that name entries in this format are coded as big-endian UCS-2 character codes only.

TT_PLATFORM_MACINTOSH

Used by Apple to indicate a MacOS-specific charmap and/or name entry. See TT_MAC_ID_XXX for corresponding 'encoding_id' values. Note that most TrueType fonts contain an Apple roman charmap to be usable on MacOS systems (even if they contain a Microsoft charmap as well).

TT PLATFORM ISO

This value was used to specify ISO/IEC 10646 charmaps. It is however now deprecated. See TT_ISO_ID_XXX for a list of corresponding 'encoding_id' values.

TT PLATFORM MICROSOFT

Used by Microsoft to indicate Windows-specific charmaps. See TT_MS_ID_XXX for a list of corresponding 'encoding_id' values. Note that most fonts contain a Unicode charmap using (TT_PLATFORM_MICROSOFT, TT_MS_ID_UNICODE_CS).

TT_PLATFORM_CUSTOM

Used to indicate application-specific charmaps.

TT PLATFORM ADOBE

This value isn't part of any font format specification, but is used by FreeType to report Adobe-specific charmaps in an FT_CharMapRec structure. See TT_ADOBE_ID_XXX.

CHAPTER 4

Release notes

4.1 0.4.1

- Fixed a bug in Face.load_char
- Added get_format and get_fstype in Face (titusz.pan)

4.2 0.3.3

- Fixed a bug in get_kerning
- Added test against freetype version for FT_ReferenceFace and FT_Get_FSType_Flags

4.3 0.3.2

- Added wordle.py example
- Added get_bbox for Outline class
- Added get_cbox for Outline and Glyph classes
- Added __del__ method to Face class
- Set encoding (utf-8) to all source files and examples.
- Added test against freetype version for FT_Library_SetLcdFilterWeights.

4.4 0.3.1

• Added FT_Stroker bindings (enums, structs and methods)

Freetype Python Documentation, Release 0.4.1

- Added ft-outline and ft-color examples
- Fixed first/next char in Face
- Pythonic interface has been documented

4.5 0.3.0

• Added ftdump.py demo and necessary functions

4.6 0.2.0

- Added sfnt functions
- Added TT_XXX flags in ft_enums
- New examples

4.7 0.1.1

- · Initial release
- Working examples
